

# Net zero by 2050

The UK government has set a target of reducing greenhouse gas (GHG) emissions to net zero by 2050. Net zero implies that an amount of GHGs must be removed from the atmosphere by natural (such as forests, oceans and peatlands) and artificial methods such as carbon capture and storage (CCUS) that is equal to, or greater than, the emissions produced (for example by burning fossil fuels). We will only be able to remove a very small amount of GHGs from the atmosphere so need to reduce emissions that are produced as much as possible.

### The target of net zero by 2050 is needed to

limit global warming to +1.5°C

### Net zero is used as a target rather than aiming to eliminate all emissions

**Capture Usage** 

and Storage

but CCUS alone is **not** 

able to capture all the CO2

that we currently produce.

## A deadline of 2050 might seem like a long time away

announced a plan to **reduce** GHG emissions by at least 68%

Reducing our GHG emissions is necessary but won't be easy. Modern economies are reliant on burning fossil fuels for energy and on manufacturing processes that release GHGs directly.

**Carbon budgets** 

released so much extra CO<sub>2</sub>

## CO<sub>2</sub> is the main GHG emitted by human activities.

# Net zero requires huge changes

The government has targets called 'carbon budgets' that

show how much we can emit in a five year period. These

budgets are set 12 years ahead of time to provide long-term

that we remain on target to reach net zero well before 2050.

Since 2008, five carbon budgets have been put into law.

of emissions from international aviation and shipping.

guidance to investors. Carbon budgets are needed to ensure

Based on projections, the UK is set to miss its fourth and fifth

carbon budgets. The sixth budget (2033-37) is the first one set

in line with the net-zero target and which calls for the inclusion

means that we must transform (renew, upgrade, install and secure) entire parts of the UK's national

#### How are emissions measured?

CO<sub>2</sub> is actually only one of several important GHGs (others include fluorinated gases, nitrogen oxides and methane). Total GHG emissions are usually shown in units of CO<sub>2e</sub>, which means the global warming potential of a GHG is measured and converted into a CO<sub>2</sub> equivalent.

but this transformation also has the potential to bring many social and economic benefits

#### What's not in net zero?

For the UK's net-zero target, emissions from international shipping and aviation are excluded because it's not easy to decide whether the importer or exporter is responsible. Also, the UK is not legally responsible for the embodied/ embedded emissions caused by producing the goods and materials we import from abroad.

The net-zero target isn't perfect. It would reward us for closing domestic manufacturing in favour of importing goods from elsewhere. Net zero GHG emissions is just one aspect of climate change; other environmental issues such as biodiversity loss, ocean acidification and pollution also need to be considered. A holistic approach is needed for a more equitable and sustainable future.

The planet can no longer absorb and store the carbon that we are emitting and so it is warming rapidly and dangerously.
